MSc in Data Science

1 Introduction

This report will briefly discuss the theoretical background, implementation details and decisions taken for the construction of MLP models for sentiment analysis and POS tagging tasks.

This report and its associated code, analysis and results were conducted by the two authors. Specifically, the sentiment analysis task was performed by Drouzas Vasilis, and the POS-tagging task by Tsirmpas Dimitris. This report was written by both authors.

Note that due to the relative custom code complexity, most of the code used in this section was developed and imported from python source files located in the ‘tasks’ module. In-depth documentation and implementation details can be found in these files.

2 POS Tagging

POS tagging is a language processing task where words in a given text are assigned specific grammatical categories, such as nouns, verbs, or adjectives. The objective is to analyze sentence structure.

In this section we describe how we can leverage pre-trained word embeddings to create a context-aware MLP classifier.

2.1 Dataset

Acquiring and preprocessing our data with the goal of eventually acquiring a sufficient representation of our text is the most difficult and time-consuming task. We thus split it in distinct phases:

- Original dataset acquisition and parsing
- Qualitative analysis and preprocessing
- Transformation necessary for the NLP task

Each of these distinct steps are individually analyzed below.

2.1.1 Acquisition

We select the [English EWT-UD](#) tree, which is the largest currently supported collection for POS tagging tasks for the English language.

This corpus contains 16622 sentences, 251492 tokens and 254820 syntactic words, as well as 926 types of words that contain both letters and punctuation, such as ‘s, n’t, e-mail, Mr., ’s, etc). This is markedly a much higher occurrence than its siblings, and therefore may lead to a slightly more difficult task.

The dataset is made available in `conllu` format, which we parse using the recommended `conllu` python library. We create a dataframe for every word and its corresponding POS tag and link words belonging to the same sentences by a unique sentence ID. The data are already split to training, validation and test sets, thus our own sets correspond to the respective split files.

We are interested in the UPOS (Universal Part of Speech) tags for English words.

Set	Count	Mean	Std	Min	25%	50%	75%	Max
Training	12544	16.52	12.55	1	7	14	23	160
Validation	2000	12.75	10.56	1	5	10	17	77
Test	2077	12.25	10.75	1	4	9	17	84

Table 1: Summary and order statistics for the number of words in the sentences of each data split.

2.1.2 Qualitative Analysis

Our training vocabulary is comprised of 17113 words. We include qualitative statistics on the sentences of our dataset in Table 1. The splits are explicitly mentioned separately because the splitting was performed by the dataset authors and not by random sampling. We would therefore like to confirm at a glance whether their data are similar.

2.1.3 Preprocessing

Given the nature of our task we can not implement preprocessing steps such as removing punctuation marks, stopwords or augmenting the dataset. Thus, the only meaningful preprocessing at this stage would be converting the words to lowercase. We believe that the context of each word will carry enough information to distinguish its POS tag regardless of case.

Another issue we need to address before continuing is that of words being part of (depending on) other words for their POS tag. Those would be words such as "don't", "couldn't" or "you're". In the standard UPOS schema these are defined as two or more separate words, where the first is represented by its standard POS tag, and the rest as part of that tag (UPOS tag "PART"). For instance, "don't" would be split into "do" and "n't" with "AUX" and "PART" tags respectively. In our dataset, these words are represented both in the manner described above followed by the full word ("don't") tagged with the pseudo-tag "_". We remove the latter representation from the working dataset.

The general algorithm to calculate the window embeddings on our dataset can be found in Algorithm 1. The algorithm uses a few external functions which are not described here for the sake of brevity. `get_window()` returns the context of the word inside a sentence, including padding where needed, `embedding()` returns the word embedding for a single word and `concatenate` returns a single element from a list of elements. The rest of the functions should be self-explanatory. Note that this algorithm does not represent the actual python implementation.

Algorithm 1 Window Embedding creation algorithm from raw-text sentences.

Input sentences, window_lim: a list of sentences and an upper bound of windows to be computed

Output tuple(windows, targets): the window embeddings and the POS tag corresponding to the median word of each window

```
1: windows = list()
2: targets = list()
3:
4: for sentence in sentences do
5:     for word in sentence do
6:         window = get_window(word, sentence)
7:         target = get_tag(word)
8:         windows.add(window)
9:         targets.add(target)
10:    end for
11: end for
12:
13: window_embeddings = list()
14: for window in windows do
15:     if window_embeddings.size  $\geq$  window_lim then
16:         break
17:     end if
18:
19:     word_embeddings = list()
20:     for word in window do
21:         if word is PAD_TOKEN then
22:             word_embeddings.add(zeros(embedding_size))
23:         else
24:             word_embeddings.add(embedding(word))
25:         end if
26:     end for
27:     window_embedding = concatenate(word_embeddings)
28:     window_embeddings.add(window_embedding)
29: end for
30:
31: targets_vec = list()
32: for target in targets do
33:     targets_vec.add(one_hot(target))
34: end for
35:
36: return window_embeddings, targets_vec
```
